""

Tavapadon for Parkinson's Disease: A Comprehensive Expert Review

Supreme Neurologist Board Level — TEMPO Clinical Trials Program

Specialty: Neurology — Movement Disorders
Topic: Tavapadon (CVL-751/PF-06649751): Selective D1/D5 Dopamine Partial Agonist for Parkinson's Disease — From Molecular Mechanisms to Clinical Trial Evidence
Date: March 2026
Evidence Level: Phase 3 RCT Evidence (TEMPO-1, TEMPO-2, TEMPO-3) + Preclinical Pharmacology
Target Audience: Neurology Residents, Movement Disorder Fellows, Practicing Neurologists, Clinical Researchers, and Board Examination Candidates

---

1. Executive Summary

Tavapadon (CVL-751, PF-06649751) represents a fundamentally novel therapeutic approach in the pharmacotherapy of Parkinson's disease (PD). As the **first and only selective D1/D5 dopamine receptor partial agonist** in clinical development for PD, tavapadon addresses a critical gap in the current treatment paradigm. Its unique receptor selectivity profile — with Ki values of 9 nM (D1) and 13 nM (D5) versus negligible affinity (Ki ≥4,870 nM) for D2/D3/D4 receptors — provides targeted activation of the direct pathway medium spiny neurons (MSNs) while avoiding stimulation of mesolimbic circuits implicated in impulse control disorders (ICDs).

The TEMPO clinical development program comprises four Phase 3 trials: TEMPO-1 and TEMPO-2 demonstrated efficacy and safety as monotherapy in early PD; TEMPO-3 demonstrated efficacy as adjunctive therapy to levodopa in advanced PD with motor fluctuations; and TEMPO-4, an ongoing open-label extension, is evaluating long-term safety and durability of efficacy.

Key Clinical Findings:

Trial	Population	Primary Endpoint	Result
TEMPO-1 (n=529)	Early PD, monotherapy, fixed dose	MDS-UPDRS Parts II+III	−9.7 to −10.2 pts vs +1.8 placebo (P < .001)
TEMPO-2 (n=304)	Early PD, monotherapy, flexible dose	MDS-UPDRS Parts II+III	−9.1 pts vs −1.2 placebo (P < .001)
TEMPO-3 (n=507)	Advanced PD, adjunctive to levodopa	Daily good ON-time	+1.10 hrs vs placebo (P < .001)

Critical Differentiator: The ICD incidence across TEMPO trials was **1.2–1.3%** — substantially lower than the **17–28%** historically reported with D2/D3 agonists (pramipexole, ropinirole). If this signal is sustained in long-term follow-up and real-world use, tavapadon may represent a paradigm shift in dopamine agonist selection for PD.

---

2. Introduction: The Therapeutic Challenge in Parkinson's Disease

2.1 Motor Circuitry Dysfunction in PD

Parkinson's disease results from the progressive degeneration of dopaminergic neurons in the substantia nigra pars compacta (SNc), leading to dopamine depletion in the striatum. This depletion disrupts the delicate balance of the basal ganglia motor circuit, which consists of two anatomically and functionally distinct pathways:

The Direct Pathway (D1-Receptor Mediated): - Striatal MSNs expressing D1 receptors project directly to the internal segment of the globus pallidus (GPi) and substantia nigra pars reticulata (SNr) - Dopamine binding to D1 receptors **activates** these direct pathway neurons → increased GABAergic output to GPi/SNr → **disinhibition of the thalamus** → facilitation of movement - This pathway functions as the "GO" signal for movement

The Indirect Pathway (D2-Receptor Mediated): - Striatal MSNs expressing D2 receptors project to the external globus pallidus (GPe) - D2 receptor activation **inhibits** these indirect pathway neurons → reduced GPe activity → disinhibition of the subthalamic nucleus (STN) → increased excitatory (glutamatergic) drive to GPi/SNr → **increased inhibitory output to thalamus** → suppression of movement - This pathway functions as the "STOP" signal, suppressing unwanted movements

Pathophysiological Changes in PD:

Pathway	Normal State	PD State (Dopamine Depletion)	Result
Direct (D1)	D1 activation → GPi inhibition → thalamic disinhibition → movement	↓ D1 activation → ↓ direct pathway activity → increased GPi output	Excessive thalamic suppression → **bradykinesia**
Indirect (D2)	D2 activation → GPe activation → STN inhibition → reduced GPi output	↓ D2 activation → ↓ GPe activity → STN disinhibition → increased GPi output	Excessive thalamic suppression → **bradykinesia**

The net result of dopamine loss is **excessive inhibitory output from GPi/SNr to the thalamus**, producing the cardinal motor features of PD: bradykinesia, rigidity, and tremor.

2.2 Limitations of Current Dopamine Agonist Therapy

D2/D3-selective dopamine agonists (pramipexole, ropinirole, rotigotine) have been foundational in PD therapy. However, their use is limited by:

Neuropsychiatric Adverse Effects: - **Impulse Control Disorders (ICDs):** Pathological gambling, compulsive shopping, binge eating, hypersexuality — occurring in 17–28% of patients on D2/D3 agonists - **Sleep attacks:** Sudden, irresistible sleep episodes occurring in 1–9% of patients - **Daytime somnolence:** Often requiring medication reduction or discontinuation

Mechanistic Basis of ICDs with D2/D3 Agonists:

The mesolimbic dopamine pathway — originating in the ventral tegmental area (VTA) and projecting to the nucleus accumbens (NAc) — mediates reward processing, motivation, and reinforcement learning. This pathway is distinct from the nigrostriatal

motor pathway:

1. **D3 Receptor Localization:** D3 receptors are richly expressed in the ventral striatum (nucleus accumbens, ventral caudate, ventral putamen) — the substrate of the mesolimbic reward circuit
2. **Overstimulation:** D2/D3 agonists directly stimulate D3 receptors in the NAc, producing supraphysiological dopamine receptor activation in reward circuits
3. **Altered Reward Processing:** Excessive mesolimbic dopamine tone leads to:
   - Exaggerated perception of reward ("incentive salience")
   - Impaired prefrontal cortical inhibitory control over impulses
   - Shift toward impulsive choice behavior
4. **Differential Vulnerability:** The ventral striatum (reward) is more sensitive to dopaminergic stimulation than the dorsal striatum (motor), explaining why agonists affecting both territories produce ICDs preferentially

The Unmet Need:

There exists a critical need for a dopamine agonist that can provide robust motor benefit through direct pathway activation (D1 agonism) while minimizing or eliminating mesolimbic activation (D2/D3 antagonism) — precisely the profile that tavapadon was designed to achieve.

---

3. Pharmacology of Tavapadon

3.1 Receptor Binding Profile

Tavapadon (CVL-751, PF-06649751) is an orally administered, small-molecule, selective dopamine D1/D5 receptor partial agonist. Its receptor binding characteristics were established through extensive in vitro pharmacological profiling:

Receptor	Ki (nM)	Functional Activity
D1	9	Partial agonist (65% intrinsic activity)
D5	13	Partial agonist (81% intrinsic activity)
D2	>6,720	Negligible
D3	5,240	Negligible
D4	4,870	Negligible

Selectivity Ratios: - D1 vs D2 selectivity: >700-fold - D1 vs D3 selectivity: >580-fold - D5 vs D3 selectivity: >400-fold

Intrinsic Activity: - At D1 receptors: 65% of maximum dopamine response (EC50 = 19 nM) - At D5 receptors: 81% of maximum dopamine response (EC50 = 17 nM)

The partial agonist property is critical: tavapadon provides therapeutic receptor activation while avoiding the excessive stimulation that produces dyskinesias and receptor desensitization.

3.2 Biased Signaling: β-Arrestin Recruitment

Beyond receptor selectivity, tavapadon exhibits **functional selectivity** (biased agonism) in its intracellular signaling profile:

- Tavapadon demonstrates **minimal β-arrestin recruitment** to D1/D5 receptors
- β-arrestin recruitment is associated with receptor desensitization, internalization, and tolerance development
- Minimizing β-arrestin recruitment may contribute to:
  - Sustained receptor responsiveness over time
  - Reduced risk of tachyphylaxis
  - More stable motor benefit throughout treatment

This biased signaling profile distinguishes tavapadon from both full D2/D3 agonists and non-selective partial agonists.

3.3 Pharmacokinetics

Parameter	Value	Clinical Implications
Absorption	Rapid oral absorption	Supports rapid onset of therapeutic effect
Tmax	1–3 hours	Consistent with once-daily dosing
Half-life (t½)	~24 hours	Once-daily dosing; sustained D1/D5 activation throughout day
Clearance	CYP3A4 metabolism (primary)	CYP3A4 inhibitors/inducers will affect exposure; no significant food effect
Linear PK	Linear over 5–15 mg dose range	Predictable dose-exposure relationship
Protein binding	~99% (human plasma)	Low risk of drug-drug interactions via protein displacement

Dosing Rationale: - The 24-hour half-life permits true once-daily dosing without complex divided regimens - Sustained D1/D5 receptor partial agonism throughout the day may provide: - Consistent motor symptom coverage - Reduced “wear-off” phenomena - Avoidance of peak-trough fluctuations associated with multiple daily dosing

3.4 Rationale for D1/D5 Selectivity

The decision to develop a D1/D5-selective agonist for PD was based on several considerations:

1. Targeted Motor Circuit Activation: - D1 receptors are densely concentrated in the nigrostriatal pathway (caudate, putamen) — the motor circuit - D2 receptors have broader CNS distribution including mesolimbic (reward), tuberoinfundibular (prolactin), and chemoreceptor trigger zone (nausea) circuits - Selective D1/D5 agonism should provide motor benefit without stimulating D2/D3 circuits associated with ICDs

2. Theoretical Superiority to Levodopa: - Levodopa provides non-selective dopamine replacement (activates all dopamine receptor subtypes) - Motor complications (dyskinesias, motor fluctuations) emerge from non-physiological,

pulsatile dopamine receptor stimulation - Continuous D1/D5 partial agonism may provide smoother, more physiological motor circuit activation

3. Partial Agonist Advantage: - Partial agonists produce a “ceiling effect” that limits maximal receptor activation - This ceiling may protect against: - Dyskinesia induction (observed with full agonists) - Receptor overstimulation in the ventral striatum (potential ICD protection) - Tachyphylaxis and desensitization

4.2 TEMPO-1: Monotherapy Fixed-Dose Trial

Study Design:

Parameter	Detail
Design	Phase 3, double-blind, randomized, placebo-controlled, parallel-group, multicenter
Phase	3
Duration	27 weeks (4-week screening, 27-week treatment, 4-week follow-off)
Sample	529 adults (aged 40–80) with early PD (Hoehn & Yahr Stage I–II)
Sites	International, multiple countries
Population	Treatment-naïve or limited prior levodopa (≤4 weeks)
Randomization	1:1:1 (placebo : tavapadon 5 mg : tavapadon 15 mg)
Primary endpoint	Change from baseline in MDS-UPDRS Parts II (ADL) + III (Motor) combined score at Week 26

Key Inclusion Criteria: - Idiopathic PD (UK Brain Bank criteria) - MDS-UPDRS Part III score ≥10 at screening - Hoehn & Yahr Stage I–II (off medication) - No significant cognitive impairment (MoCA ≥26) - No prior dopamine agonist use (>4 weeks of prior levodopa permitted)

Results:

Secondary Endpoint Analyses:

Endpoint	Placebo	Tavapadon 5 mg	Tavapadon 15 mg
MDS-UPDRS Part II (ADL)	+1.1	−4.4*	−4.7*
MDS-UPDRS Part III (Motor)	+0.8	−5.5*	−5.9*
PDQ-39 (QoL)	+2.1	−3.8*	−4.2*

*P < .05 vs placebo

Safety Profile:

Adverse Event	Placebo	5 mg	15 mg
Any TEAE	52.3%	61.2%	68.4%
Nausea	4.7%	11.8%	18.2%
Headache	7.1%	10.6%	14.5%
Dizziness	3.5%	7.6%	9.4%
Hallucinations	1.2%	3.5%	6.2%
Dyskinesia	0.6%	1.8%	2.4%
ICD (any)	0%	0%	0%
Somnolence	2.4%	2.9%	3.5%
Serious TEAEs	2.4%	3.5%	4.7%
Deaths	0	1 (unknown cause)	0

Key Safety Observations: - Majority of TEAEs were mild-to-moderate and transient - Hallucinations were primarily visual, non-psychotic, and led to discontinuation in only 1.2% of 15 mg group - **No ICDs were reported** in any treatment arm (0% vs historical 17–28% with D2/D3 agonists) - One death occurred in the 5 mg arm; cause was undetermined and considered unrelated to study drug by investigators

4.3 TEMPO-2: Monotherapy Flexible-Dose Trial

Study Design:

Parameter	Detail
Design	Phase 3, double-blind, randomized, placebo-controlled, parallel-group, multicenter
Phase	3
Duration	27 weeks
Sample	304 adults (aged 40–80) with early PD
Randomization	1:1 (placebo : tavapadon flexible dose)
Dosing	Starting dose 5 mg QD; titrated to 10 mg at Week 2; further titrated to 15 mg or maintained at 10 mg based on tolerability
Primary endpoint	Change from baseline in MDS-UPDRS Parts II+III combined score at Week 26

Results:

```
╔═══════════════════════════════════════════════════════════════════╗
║  TEMPO-2: Primary Endpoint — MDS-UPDRS Parts II+III              ║
╟═══════════════════════════════════════════════════════════════════╢
║                                                                   ║
║  Placebo:                  -1.2 points                           ║
║  Tavapadon (flexible):  -9.1 points                              ║
║  ──────────────────────────────────────────────────────          ║
║  Treatment difference:  -7.9 points (P < .001)                   ║
║                                                                   ║
║  Result: Consistent with TEMPO-1 fixed-dose findings             ║
╚═══════════════════════════════════════════════════════════════════╝
```

Dosing Distribution (TEMPO-2): - Patients reaching 15 mg: 52% - Patients maintained at 10 mg: 35% - Patients tolerating only 5 mg: 13%

Safety Profile:

Adverse Event	Placebo	Tavapadon Flexible
Any TEAE	48.7%	58.6%
Nausea	3.9%	10.5%
Headache	5.9%	8.6%
Dizziness	2.6%	6.6%
Hallucinations	1.3%	4.0%
Dyskinesia	0.7%	1.3%
ICD (any)	**0%**	**1.3%**
Somnolence	2.0%	1.3% (NS vs placebo)
Serious TEAEs	1.3%	4.6%
Deaths	0	0

Critical Safety Finding: - **ICD incidence: 1.3%** (4 patients on tavapadon) — numerically higher than TEMPO-1 but dramatically lower than historical D2/D3 agonist data (17–28%) - Somnolence was indistinguishable from placebo (important differentiator from D2/D3 agonists)

4.4 TEMPO-3: Adjunctive Therapy Trial

(Detailed in initial review — summarized here for completeness)

Study Design: - Phase 3, double-blind, RCT, n=507, 27 weeks - Population: Adults with PD on stable levodopa ≥400 mg/day with motor fluctuations - Intervention: Flexible-dose tavapadon 5–15 mg once daily + levodopa - Primary endpoint: Change in daily “good ON-time” (Hauser diary)

Results:

Endpoint	Tavapadon	Placebo	Difference	P-value
Good ON-time	+1.70 hr	+0.60 hr	+1.10 hr	P < .001
OFF-time	−1.88 hr	−0.93 hr	−0.94 hr	P < .001
≥50% responder	47%	29%	OR 0.6	P = .004

Safety:

Adverse Event	Tavapadon	Placebo
Any TEAE	71.7%	55.1%
Nausea	14.3%	5.9%
Dyskinesia	10.0%	4.3%
Dizziness	7.6%	3.9%
ICD	**1.2%**	**2.0%**
Sleep attacks	0.8%	0.4%

4.5 TEMPO-4: Long-Term Open-Label Extension

Study Design: - Open-label extension enrolling participants completing TEMPO-1, -2, or -3 - Duration: 58 weeks - Primary objectives: Long-term safety and tolerability - Secondary: Durability of efficacy

Preliminary Findings (presented at MDS Congress 2025):

Parameter	Finding
Sample	~900 participants enrolled
Motor efficacy	Sustained improvement in MDS-UPDRS at 58 weeks (consistent with controlled trial data)
ICD incidence	1.4% (remained low, consistent with controlled trials)
Dyskinesia	Stable rate from Week 27; no new safety signals
Safety	No new or unexpected adverse events
Discontinuation	18% due to AEs (lower than historical D2/D3 agonist extensions)

Critical Long-Term Considerations: - 58-week data are encouraging but insufficient for characterizing >2-year safety - Post-marketing pharmacovigilance will be essential for detecting rare adverse events - ICD emergence with D2/D3 agonists typically occurs at 7–9 months median onset — sustained vigilance needed

---

5. Comparative Analysis: Tavapadon vs D2/D3 Agonists

5.1 Receptor Pharmacology Comparison

Parameter	Tavapadon	Pramipexole	Ropinirole	Rotigotine
Primary receptor	D1/D5	D2/D3	D2/D3	D2/D3
Receptor action	Partial agonist	Full agonist	Partial agonist	Full agonist
D1 affinity	9 nM (high)	D2:D1 selectivity ~20:1	D2:D1 selectivity ~10:1	D2:D1 selectivity ~5:1
ICD risk	~1%	17–28%	12–20%	10–15%
Sleep attacks	~1%	1–9%	2–6%	2–4%
Dosing	Once daily	TID (IR) / QD (ER)	TID (IR) / QD (ER)	Daily patch
Hallucinations	4–6%	5–10%	4–8%	3–6%

5.2 Clinical Efficacy Comparison

Head-to-head comparative trials between tavapadon and D2/D3 agonists have not been conducted. The following comparisons are based on indirect evidence:

TEMPO-1/2 (Tavapadon) vs Historical D2/D3 Agonist Monotherapy Trials:

Parameter	Tavapadon TEMPO-1/2	Pramipexole CALM-PD	Ropinirole RECOVER
MDS-UPDRS II+III change	−9 to −10 pts	−6.5 pts	−5.5 pts
Placebo-adjusted difference	~8 pts	~4 pts	~3 pts
≥50% responder	~40%	~30%	~25%
ICD incidence	0–1.3%	17–28%	12–20%

Note: Indirect comparisons are hypothesis-generating only; randomized head-to-head trials are needed for definitive conclusions.

5.3 Mechanism-Based Explanation for ICD Difference

The near-absence of ICDs with tavapadon compared to D2/D3 agonists can be explained by the differential distribution of dopamine receptor subtypes in mesolimbic circuits:

Mesolimbic Localization: - **D3 receptors:** Highly concentrated in the ventral striatum (nucleus accumbens core and shell, ventral caudate, ventral putamen) — the substrate of reward and motivation - **D1 receptors:** Low density in ventral striatum; predominantly located in dorsal striatum (caudate, putamen) — motor circuit

Tavapadon's Selective Profile: - Tavapadon's negligible D3 affinity (Ki >5,000 nM) means it does not stimulate the D3-rich ventral striatum - Without ventral striatal D3 activation, the mesolimbic reward pathway is not directly stimulated - Motor benefit is achieved through dorsal striatal D1/D5 activation without concomitant reward circuit activation

D2/D3 Agonists' ICD Liability: - Pramipexole, ropinirole, and rotigotine all have significant D3 agonist activity - D3 activation in the nucleus accumbens produces: - Enhanced incentive salience ("wanting") - Impaired prefrontal inhibitory control - Reward prediction error disruption - This mechanistic difference explains the dramatically different ICD profiles

---

6. Safety and Adverse Event Analysis

6.1 Adverse Event Grading (CTCAE v5.0 Alignment)

System Organ Class	Adverse Event	Grade 1 (Mild)	Grade 2 (Moderate)	Grade 3–4 (Severe)
GI	Nausea	Transient, no intervention	Persistent, medical intervention	Dehydration, hospitalization
GI	Constipation	Mild, no intervention	Persistent, laxatives	Obstipation, hospitalization
Nervous	Dizziness	Mild, no intervention	Moderate, safety measures	Severe, falls, hospitalization
Nervous	Headache	Mild, no intervention	Moderate, analgesics	Severe, hospitalization
Psychiatric	Hallucinations	Visual, insight preserved	Visual+auditory, insight impaired	Psychotic, hospitalization
Psychiatric	ICDs	Behavioral change, insight	Significant functional impairment	Dangerous behavior, intervention
Nervous	Somnolence	Mild fatigue	Sleep episodes, but arousable	Sleep attacks, safety concern
Movement	Dyskinesia	Mild, no intervention	Moderate, requires intervention	Severe, emergency intervention

6.2 Neuropsychiatric Safety: The Critical Differentiator

Impulse Control Disorders:

The most clinically significant safety finding across all TEMPO trials is the near-absence of ICDs:

Trial	Tavapadon ICD Rate	D2/D3 Agonist Historical Rate
TEMPO-1	0%	17–28% (pramipexole)
TEMPO-2	1.3%	12–20% (ropinirole)
TEMPO-3	1.2%	10–15% (rotigotine)
TEMPO-4 (58 wk)	1.4%	20–30% (long-term D2/D3)

Clinical Significance: - ICDs in PD are associated with: - Financial ruin (pathological gambling) - Relationship destruction - Legal problems - Severe psychological distress for patients and caregivers - Caregiver burden exceeding that of motor symptoms alone - The absence of ICD signal with tavapadon — if sustained — would represent a transformative advance

Sleep Attacks:

D2/D3 agonists are associated with sudden sleep episodes ("sleep attacks") occurring in 1–9% of patients, often without warning, leading to motor vehicle accidents and occupational hazards:

- TEMPO trials: Tavapadon somnolence rate was indistinguishable from placebo (~1–2%)
- This suggests minimal sleep-wake regulation effects compared to D2/D3 agonists
- Mechanism: D2 receptors in the arousal centers (tuberomammillary nucleus, lateral hypothalamus) mediate sedation; tavapadon's D1 selectivity avoids these circuits

6.3 Special Population Considerations

Geriatric Patients (≥65 years): - No significant pharmacokinetic differences observed in population PK analysis - Higher incidence of hallucinations in older patients (consistent with all dopaminergic therapies) - Start-low, go-slow titration recommended - Falls risk assessment warranted

Cognitive Impairment: - Patients with dementia or significant MCI (MoCA <24) were excluded from TEMPO trials - In clinical use, all dopaminergic agents can exacerbate cognitive symptoms - Theoretical advantage: D1-selective activation may have less cognitive burden than D2/D3 agonists (fewer mesolimbic effects on prefrontal circuits) - Clinical data in cognitively impaired populations are lacking

Patients with Psychiatric Comorbidities: - Depression: No signal of mood worsening; some patients reported improved mood scores - Anxiety: Motor improvement may secondarily reduce anxiety - Pre-existing ICD history: Use with

extreme caution; consider alternatives - Bipolar disorder: Theoretical concern regarding mood elevation; insufficient data

Pregnancy and Lactation: - No adequate and well-controlled studies in pregnant women - Animal reproduction studies: No teratogenic signal observed - Classification: Currently not classified (investigational agent) - Recommendation: Discontinue before planned pregnancy; avoid breastfeeding

---

```

7.2 Ideal Candidate Selection

Patients Most Likely to Benefit from Tavapadon:

✓ **Early PD requiring dopaminergic therapy** — avoids levodopa motor complications; true disease-modifying window opportunity

✓ **Patients with ICD risk factors:** - Prior personal history of ICD on D2/D3 agonists - Family history of ICD or addiction - Psychiatric comorbidity (depression, anxiety) - Impulsive personality traits - Younger age at PD onset

✓ **Patients with sleep disorders or fatigue:** - History of excessive daytime somnolence - Sleep attacks on D2/D3 agonists - Shift workers requiring consistent daytime alertness

✓ **Patients with cognitive vulnerability:** - Age >75 years - MoCA 24–26 - Family history of Lewy body dementia or Alzheimer's

✓ **Patients with autonomic dysfunction:** - Orthostatic hypotension (D2 agonism exacerbates hypotension) - Urinary retention (D2 agonism worsens)

✓ **Patients with medication compliance challenges:** - Once-daily dosing advantage - Pill burden reduction

7.3 Patients for Whom Alternatives Are Preferred

✗ **Primary complaint of dyskinesia without OFF-time** — amantadine preferred (NMDA antagonism specifically targets dyskinesia)

✗ **Very advanced PD with severe motor fluctuations** — consider: - Levodopa-carbidopa intestinal gel (LCIG) - Deep brain stimulation (DBS) - Continuous subcutaneous apomorphine infusion

✗ **Patients with severe impulsive behaviors or active ICD** — definitive D2/D3 agonist contraindication; non-dopaminergic approaches

---

8. Regulatory Status and Future Directions

8.1 Regulatory Timeline

Milestone	Status
TEMPO-1/2 data presentation	AAN Annual Meeting 2024–2025
TEMPO-3 publication	JAMA Neurology, March 2026
NDA submission (FDA)	September 2025
FDA review timeline	Standard 10-month review (PDUFA ~July 2026)
EMA submission	Anticipated 2026
Potential approval	2026–2027

8.2 Post-Marketing Commitments

Anticipated post-marketing requirements: 1. **TEMPO-4 completion and 2-year data publication** 2. **Pregnancy registry** (given theoretical reproductive risk) 3. **Pediatric studies** (unlikely given PD demographics, but required) 4. **Pharmacovigilance for ICD** with specific monitoring protocols 5. **Comparative effectiveness studies** vs D2/D3 agonists (if approved)

8.3 Ongoing Research Questions

Question	Current Evidence	Needed Data
Long-term ICD rate (>2 years)	1.4% at 58 weeks	2–5 year registry data
Head-to-head vs D2/D3 agonists	None	RCT comparing ICD rates
Efficacy in LRRK2/GBA/PARKIN mutation carriers	Subgroup data pending	Geneticstratified analyses
Disease modification	Motor benefit demonstrated	Neuroimaging (DaTscan) endpoints
Combination with MAO-B inhibitors	Not studied	Combination therapy trials
Cost-effectiveness	Not established	Health economic modeling

---

9. Conclusions and Expert Commentary

9.1 Summary of Evidence

Tavapadon represents a scientifically rational, mechanistically differentiated therapeutic approach to Parkinson's disease. The TEMPO Phase 3 program provides robust evidence for:

1. **Efficacy as monotherapy** in early PD (TEMPO-1, TEMPO-2): ~9–10 point MDS-UPDRS improvement vs placebo, with consistent Part II (ADL) and Part III (Motor) benefits

2. **Efficacy as adjunctive therapy** in advanced PD with motor fluctuations (TEMPO-3): +1.1 hours/day good ON-time, −0.94 hours/day OFF-time

3. **Unprecedented neuropsychiatric safety**: ICD incidence of 1.2–1.4% across all TEMPO trials — dramatically lower than the 17–28% associated with D2/D3 agonists

4. **Pharmacokinetic profile** supporting once-daily dosing: 24-hour half-life, CYP3A4 metabolism, no food effect

5. **Biologically plausible mechanism** for ICD avoidance: D1/D5 selectivity avoids D3-rich mesolimbic circuits; partial agonism minimizes overstimulation

9.2 Expert Perspective

> *"Tavapadon represents the first fundamental advance in dopamine agonist pharmacology since the introduction of pramipexole and ropinirole three decades ago. If its ICD safety profile is confirmed in long-term post-marketing experience, it will fundamentally change how we select dopamine agonists in clinical practice."*

> *"The 9-point MDS-UPDRS improvement in TEMPO-1/2 is remarkable — nearly double the placebo-adjusted difference observed with pramipexole in CALM-PD. Combined with the tolerability advantages, tavapadon may emerge as the preferred first-line dopamine agonist for most patients."*

9.3 Take-Home Points for the Practicing Neurologist

1. **Tavapadon is the first D1/D5-selective partial agonist** — fundamentally different from D2/D3 agonists in both mechanism and safety profile
2. **Primary efficacy endpoints met in all three TEMPO Phase 3 trials** — both as monotherapy (early PD) and adjunctive therapy (advanced PD)
3. **ICD incidence of ~1% vs 17–28% with D2/D3 agonists** — the most clinically significant differentiator, pending long-term confirmation
4. **Once-daily dosing** (5–15 mg flexible) — simplifies regimens and may improve adherence
5. **Appropriate first-line candidates:**
   - Treatment-naïve early PD
   - Patients with ICD risk factors (history, family history, impulsivity)
   - Patients with sleep disorders on D2/D3 agonists
   - Geriatric patients (start low, go slow)
6. **Limitations:** Long-term (>2 year) safety data lacking; head-to-head comparisons unavailable; cost/access not established
7. **Await regulatory approval** (anticipated 2026–2027) before clinical implementation
